What

This week looked up how to assign random numbers id to an account, since this how real banking systems assign IDs to user accounts, in my database the accounts had sequential ids assigned to them. I used the script from https://www.uuidgenerator.net/dev-corner/php#google_vignette, to assign randomised ids to the accounts. Next I updated the transaction page, it previously was showing the account ID of the user's involved in the transaction. Then I added an option for the user to set an account as default, the account set as default is the account that is going to be receiving money whenever moneys sent to the user. Lastly I updated the form that user uses to send money to someone, previously it needed the account ID of the receiver, now it requires the username instead.

So What

I made most of these changes for security reason, using sequential ids for the accounts was risky, since a malicious user could have better understanding of how the accounts are stored in the database and exploit this knowledge to target specific accounts. The transaction page showing the id of the sender and the receiver, was bad too since I was exposing a details of theses users that should stay hidden and it also wasn't user friendly, since the user cant really tell who sent them money. I added the default account setting for simplicity. If the user wanted to send money to someone, they would need to know which account to send it to in case the receiver had created multiple. This setting allows the receiver to set an account as default, and then they will decided to which account to transfer their money.

Now What

Going forward, I will continue focusing on improving the security and user experience of the system. For example, I may review other areas where internal database information might still be exposed and ensure it is properly protected. I also plan to test the new username based transaction system thoroughly to make sure it handles edge cases, such as users with similar names or invalid usernames. Additionally, I may explore adding further validation and error handling to make the transaction process safer and more reliable.
