What

We talked about systems thinking. We did research on the incident that happened to Knight Capital. This gave us insight of how the absence of rigorous security tests and a lack of contingency plan can be disastrous for a company. We were tasked to build a system for the company and try to think of human errors, natural disasters that can can happen and try to prevent these issues or at least mitigate the damage.

So What

The knight capital disaster demonstrated the importance of system thinking, because the accident was caused by multiple factors. Such as leaving vulnerable legacy code, low staff since there was only one engineer tasked to setup the new system, also the company didnt store any data they could rollback to and lastly they also ignored the warning messages and reacted to them when it was too late.We used this disaster as example of accidents that we need to prevent when building our own system.

Now What

From now I will give even more priority to the security of my project. My project is a cash transfer web application, as of now most of the web forms I have implemented lack input validation, and some sql statements dont use prepared statements, so this makes my application vulnerable to SQL injections, but I will act on them and put in place the adequate measures to prevent this from happening.
